CallShield India

Multilingual scam detection powered by Gnani

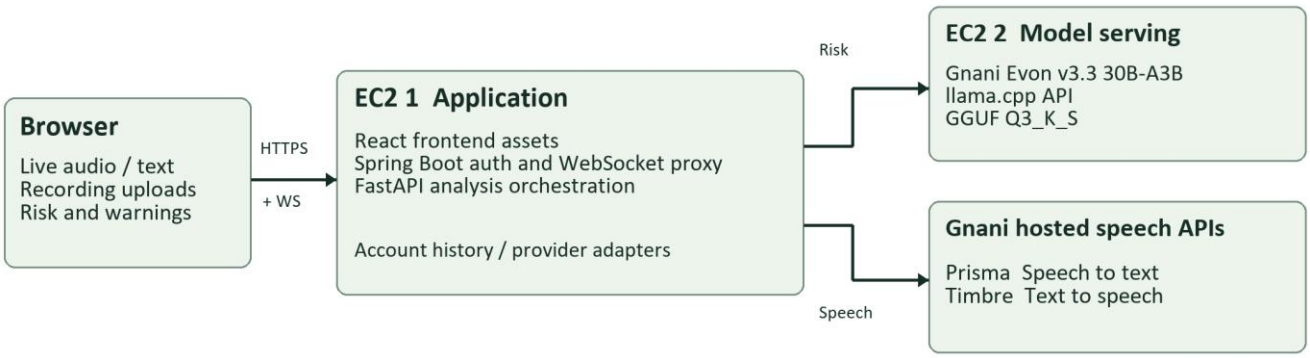

“Share the OTP now, or your account will be blocked.”

A familiar request becomes dangerous when authority, urgency and pressure enter the conversation. CallShield is built for that moment: helping people recognise suspicious behaviour while they still have a chance to pause, refuse and verify.

From conversation to an informed decision: Users can stream consented microphone audio, upload a recording or review text. As speech is transcribed and inference completes, CallShield updates a 0-100 risk index, five suspicion bands and a concise explanation with supporting transcript quotes. Configurable thresholds, hysteresis and cooldowns limit repeated alerts. Saved history lets users revisit the evidence.

Gnani powers the complete workflow: Prisma transcribes speech across ten supported audio locales. Evon assesses conversational context and suspicious intent, with evidence retained in the original script and selectable explanation language. Timbre voices curated English and Hindi safety guidance. Hindi and Hinglish support bring the experience closer to how users actually speak.

Deployed architecture

Streaming designed around real inference: The browser sends 16 kHz mono PCM audio through an authenticated WebSocket gateway. Completed transcript turns feed a bounded context window; new speech arriving during inference is coalesced into the next assessment. The server validates structured model output and checks evidence quotes against the transcript. Provider keys stay on the servers.

A deployed prototype with a reproducible demo: The separate model instance serves Evon v3.3 30B-A3B through llama.cpp using a community GGUF conversion from Hugging Face, without fine-tuning and with internal reasoning disabled. Our fictional Hinglish demo is also generated using Timbre v2.5: Nalini voices the caller and Vikrant the recipient. Modular adapters and an explicitly labelled offline mock mode support development and testing.

The goal is a safer next decision: CallShield gives users evidence they can inspect and guidance they can hear before sharing a code or acting under pressure. Risk indices are uncalibrated assessments, not fraud probabilities; independent accuracy evaluation remains necessary.
